

An involution of reals, discontinuous on rationals and whose derivative vanish almost everywhere

A. Muhammed Uludağ*, Hakan Ayrıl*

March 18, 2018

Abstract

We study the involution of the real line, induced by Dyer's outer automorphism of $\mathrm{PGL}(2, \mathbf{Z})$. It is continuous at irrationals with jump discontinuities at rationals. We prove that its derivative exists almost everywhere and vanishes almost everywhere.

1 Introduction

A function discontinuous on a dense subset of $[0, 1]$ can not be differentiable everywhere on the residual set; it can be differentiable at most on a meager set (i.e. a countable union of nowhere dense sets), see [1]. However, meager does not mean negligible: there exists meager sets of full Lebesgue measure, and it was also exhibited in the location cited a function discontinuous at rationals and yet differentiable on a set of full measure.

In this paper we show that, the involution \mathbf{J} (Jimm) recently introduced by us in [5], [4] is of this kind: it has jump discontinuities at rationals, it is differentiable almost everywhere and has a derivative vanishing almost everywhere.

This involution satisfies a set of functional equations of “modular type”

$$\mathbf{J}(1-x) = 1 - \mathbf{J}(x), \quad \mathbf{J}(1/x) = 1/\mathbf{J}(x), \quad \mathbf{J}(-x) = -1/\mathbf{J}(x),$$

where $x \in \mathbf{R} \setminus \mathbf{Q}$. These equations shows that \mathbf{J} is induced by Dyer's outer automorphism of the group $\mathrm{PGL}_2(\mathbf{Z})$. In fact these equations characterize the

*Galatasaray University, Department of Mathematics, Çırağan Cad. No. 36, 34357 Beşiktaş İstanbul, Turkey

involution as one can compute $\mathbf{J}(x)$ by using these equations. A working definition in terms of continued fractions is given in the next section.

Besides its curious analytic nature, \mathbf{J} has many important arithmetic and dynamical properties, for example; it preserves the set of quadratic irrationals commuting with the Galois conjugation on them [5]; conjecturally sends algebraic numbers of degree > 2 to transcendental numbers [?], conjugates the Gauss continued fraction map to the so-called Fibonacci map [?] and induces a subtle symmetry of Lebesgue's measure [6].

As a consequence of the above functional equations, \mathbf{J} preserves the harmonic pairs of numbers:

$$\frac{1}{x} + \frac{1}{y} = 1 \iff \frac{1}{\mathbf{J}(x)} + \frac{1}{\mathbf{J}(y)} = 1.$$

showing that \mathbf{J} induces a duality of Beatty partitions of the set of positive integers [4]. We refer the reader to [4] and to [6] for a wider perspective about \mathbf{J} .

Since \mathbf{J} is discontinuous on \mathbf{Q} , we leave it undefined there (though there is [6] a version of it defined on $\mathbf{Q} \setminus \{0\} \rightarrow \mathbf{Q} \setminus \{0\}$). It sends the noble numbers \mathcal{N} (see below) to \mathbf{Q} in a 2-to-1 manner. It restricts to an involution of $\mathbf{R} \setminus (\mathbf{Q} \cup \mathcal{N})$ preserving the unit interval. Here, we shall work with the restriction of \mathbf{J} to the unit interval. Our result is also valid for its extension to \mathbf{R} .

Since the derivative of \mathbf{J} vanishes on an uncountable set, and since it is involutive, its derivative is infinite on an uncountable set (of zero measure). It is of interest to know about other possible values attained by the derivative.

In fact, the outer automorphism of $\mathrm{PGL}_2(\mathbf{Z})$ acts on the bipartite Farey tree \mathcal{F} inducing a perfectly well defined homeomorphism of its boundary. As described in [4], this homeomorphism in turn induces the involution \mathbf{J} in this paper. Every \mathcal{F} -automorphism induces a map $\mathbf{R} \rightarrow \mathbf{R}$ this way, which is well-defined and continuous except on a countable set. In a wider context, the result of this paper can be seen as a first step in understanding the analytical properties of the functions induced by tree morphisms. To our knowledge, these questions have been largely overlooked in the literature. For example, it is of interest to know about the \mathcal{F} -automorphisms which induce absolutely continuous functions.

2 Introducing the involution

As usual, denote the continued fraction $1/(n_1 + 1/\dots)$ by $[0, n_1, n_2, \dots]$. Let $x = [0, n_1, n_2, \dots]$ be a number with $2 \leq n_1, n_2 \cdots < \infty$. Then the value that \mathbf{J} takes on x is defined as

$$\mathbf{J}(x) = \mathbf{J}([0, n_1, n_2, \dots]) := [0, 1_{n_1-1}, 2, 1_{n_2-2}, 2, 1_{n_3-2}, \dots], \quad (1)$$

where 1_k denotes the sequence $1, 1, \dots, 1$ of length k . This formula extends to all positive irrational numbers, i.e. those with $x = [0, n_1, n_2, \dots]$ satisfying $1 \leq n_1, n_2 \dots < 1$, if the emerging 1_{-1} 's are eliminated in accordance with the rule $[\dots m, 1_{-1}, n, \dots] = [\dots m + n - 1, \dots]$ and 1_0 with the rule $[\dots m, 1_0, n, \dots] = [\dots m, n, \dots]$. The last rule comprises the case $[1_0, n, \dots] = [n, \dots]$.

See [4], [5] for a computation of some values of \mathbf{J} .

From its definition it is readily seen that \mathbf{J} sends ultimately periodic continued fractions (i.e. quadratic irrationals) to itself. As the examples below indicates, it is highly non-trivial on the set of quadratic irrationals.

$$\mathbf{J}(\sqrt{3}) = \frac{1}{2}(\sqrt{13} + 3), \quad \mathbf{J}(\sqrt{5}) = \frac{1}{3}(\sqrt{10} + 1), \quad \mathbf{J}(\sqrt{6}) = \frac{1}{14}(\sqrt{221} + 5).$$

In particular, if x is the reciprocal of the golden ratio, i.e. $x = [0, 1_\infty] = \frac{-1+\sqrt{5}}{2}$, then the definition gives

$$\mathbf{J}(x) = [0, 1_0, 2, 1_{-1}, 2, 1_{-1}, 2, \dots]$$

and applying the simplification rules we get

$$\mathbf{J}(x) = [0, 2, 1_{-2}, 2, \dots] = [0, 3, 1_{-1}, 2, \dots] = [0, 4, 1_{-1}, 2, \dots] = \dots = [0, \infty] = 0.$$

Similarly if n_i is constantly 1 from some point on, i.e. $x = [0, n_1, n_2, \dots, n_k, 1_\infty]$ with $n_k > 1$, then $\mathbf{J}(x) = [0, \dots, 1_{n_k-2}, \infty] \in \mathbf{Q}$, i.e. noble numbers are sent to rationals under \mathbf{J} . Note that

$$\begin{aligned} \mathbf{J}([0, 3, 1_\infty]) &= [0, 1_2, 2, 1_{-1}, 2, 1_{-1}, 2, \dots] = [0, 1, 1, \infty] = 1/2, \text{ and} \\ \mathbf{J}([0, 1, 2, 1_\infty]) &= [0, 1_0, 2, 1_0, 2, 1_{-1}, 2, 1_{-1}, 2, \dots] = [0, 2, \infty] = 1/2. \end{aligned}$$

In a similar manner, it is easy to see that \mathbf{J} is two-to-one on the set of noble numbers in $[0, 1]$ (except that $\mathbf{J}^{-1}(0) = [0, 1_\infty]$ and $\mathbf{J}^{-1}(1) = [0, 2, 1_\infty]$). It is bijective and involutive on the set $[0, 1] \setminus (\mathbf{Q} \cup \mathcal{N})$, where \mathcal{N} denotes the set of noble numbers (see [5]).

Figure. The graph of \mathbf{J} lies inside the smaller (and darker) boxes.

If $x = [0, n_1, n_2, \dots]$ is an irrational and $x_k = [0, n_1^{(k)}, n_2^{(k)}, \dots]$ is a sequence tending to x , then for every N , there exists an M such that $n_i^{(k)} = n_i$ for $k > N$ and $i < M$. This implies that longer and longer initial segments of $[0, \ell_1^{(k)}, \ell_2^{(k)}, \dots]$ coincides with that of $[0, \ell_1, \ell_2, \dots]$, where $\mathbf{J}(x) = [0, \ell_1, \ell_2, \dots]$ and $\mathbf{J}(x_k) = [0, \ell_1^{(k)}, \ell_2^{(k)}, \dots]$. Hence, $\mathbf{J}(x_k) \rightarrow \mathbf{J}(x)$, i.e. our involution \mathbf{J} is continuous at every irrational x .

If $x = [0, n_1, n_2, \dots, n_m, \infty]$ is a rational with m odd, let $x_k = [0, n_1^{(k)}, n_2^{(k)}, \dots]$ be a sequence tending to x from below. Then there exists an N such that $n_i^k = n_i$ for $k > N$, $i \leq m$, and $n_{m+1}^{(k)} \rightarrow \infty$. This implies that longer and longer initial segments of $[0, \ell_1^{(k)}, \ell_2^{(k)}, \dots]$ coincides with that of $\mathbf{J}_-(x) := [0, \ell_1, \ell_2, \dots]$, where $\mathbf{J}(x_k) = [0, \ell_1^{(k)}, \ell_2^{(k)}, \dots]$ and

$$[0, \ell_1, \ell_2, \dots] = [0, 1_{n_1-1}, 2, 1_{n_2-2}, 2, 1_{n_3-2}, \dots, 2, 1_{n_m-2}, 2, 1_\infty].$$

Hence, the limit $\lim_{x_k \uparrow x} \mathbf{J}(x_k)$ exists. Similarly, the limit for even m and the limit $\lim_{x_k \downarrow x} \mathbf{J}(x_k)$ exists.

3 The derivative of jimm.

It is known that for almost all x , the arithmetic mean of partial quotients of x tends to infinity, i.e. for almost all $x = [0, n_1, n_2, \dots]$ (see [2])

$$\lim_{k \rightarrow \infty} \frac{n_1 + \dots + n_k}{k} = \infty. \quad (2)$$

In other words, the set of numbers in $[0, 1]$ such that the above limit is infinite, is of full Lebesgue measure. Denote this set by A . Now since the first k partial fractions of x give rise to at most $n_1 + \dots + n_k - k$ partial fractions of $\mathbf{J}(x)$ and at least $n_1 + \dots + n_k - 2k$ of these are 1's, one has

$$\frac{n_1 + \dots + n_k - k}{n_1 + \dots + n_k - 2k} \rightarrow 1 \text{ as } k \rightarrow \infty.$$

This shows that the density of 1's in the continued fraction expansion of $\mathbf{J}(x)$ equals 1 a.e., and therefore the the continued fraction averages of $\mathbf{J}(x)$ tend to 1 a.e.. We conclude that $\mathbf{J}(A)$ is a set of zero measure.

Suppose $x = [0, n_1, n_2, \dots]$ is an irrational satisfying (2). Then for every constant M , there is some k with $n_1 + \dots + n_k > kM$. But then the \mathbf{J} -transform of the initial length- k segment of x is of length at least $kM - k$. Hence if y is any number whose continued fraction expansion coincide with that of x up to the place k , then the continued fraction $\mathbf{J}(y)$ coincide with that of $\mathbf{J}(x)$ at least up to the place $kM - k$. Since $kM - k$ is arbitrarily big compared to k , and since longer continued fractions give exponentially better approximations, we see that $\mathbf{J}(y)$ a.e. is much closer to $\mathbf{J}(x)$ than y is to x . Hence the idea of the following theorem.

Theorem 1 *The derivative of $\mathbf{J}(a)$ exists almost everywhere and vanishes almost everywhere.*

To prove this, we need to show that for almost all a ,

$$\lim_{x \rightarrow a} \frac{\mathbf{J}(a) - \mathbf{J}(x)}{a - x} = 0.$$

Assume that x is irrational or equivalently its continued fraction expansion is non-terminating.

Let $x \in [0, 1]$ with $0 < |x - a| < \delta$ for some δ . Then there is a number $k = k_\delta$, such that the continued fractions of a and x coincide up to the k th element. Hence $x = [0, n_1, n_2, \dots, n_k, m_{k+1}, \dots]$ with $m_{k+1} \neq n_{k+1}$. Note that this latter condition also guarantees that $0 < |x - a|$. Now let

$$M_k(z) := [n_1, n_2, \dots, n_{k-1}, n_k + z] = \frac{\alpha_k z + \beta_k}{\gamma_k z + \theta_k}$$

and put $a_k := [0, n_{k+1}, n_{k+2}, \dots]$, $x_k := [0, m_{k+1}, m_{k+2}, \dots]$. Then one has $0 < a_k < 1$ (with strict inequality since a is irrational) and $0 \leq x_k < 1$ for every $k = 1, 2, \dots$. One has $a = M_k(a_k)$, $x = M_k(x_k)$ and $\det(M_k) = (-1)^k$.

Lemma 2 Let $a := [0, n_0, n_1, \dots]$ and suppose that the continued fractions of a and x coincide up to the place k (but not $k + 1$), where $x \in [0, 1]$. Put $N_k := \sum_{i=1}^k n_i$, and $\mu_k := N/k$. Then

$$|a - x| > \frac{1}{24}(2\mu_{k+3})^{-2(k+3)}$$

Proof. One has

$$|a - x| = |M_k(a_k) - M_k(x_k)| = \left| \frac{\alpha_k a_k + \beta_k}{\gamma_k a_k + \theta_k} - \frac{\alpha_k x_k + \beta_k}{\gamma_k x_k + \theta_k} \right| = \frac{1}{(\gamma_k a_k + \theta_k)(\gamma_k x_k + \theta_k)}$$

Since

$$M_{i+1}(z) = M_i \left(\frac{1}{n_{i+1} + z} \right) = \frac{\beta_i z + (\alpha_i + n_{i+1} \beta_i)}{\theta_i z + (\gamma_i + n_{i+1} \theta_i)},$$

one has $\gamma_{i+1} = \theta_i$ and $\theta_{i+1} = \gamma_i + n_{i+1} \theta_i$. Hence $\theta_{i+1} > \gamma_{i+1} \implies \theta_{i+1} > \theta_i(1 + n_{i+1})$. This implies

$$\begin{aligned} \theta_i &< (1 + n_1)(1 + n_2) \dots (1 + n_i), \\ \gamma_i &< (1 + n_1)(1 + n_2) \dots (1 + n_{i-1}). \end{aligned}$$

Since $0 \leq a_k, x_k < 1$, this implies

$$\begin{aligned} \gamma_k a_k + \theta_k &< \gamma_k + \theta_k < 2(1 + n_1)(1 + n_2) \dots (1 + n_k), \\ \gamma_k x_k + \theta_k &< \gamma_k + \theta_k < 2(1 + n_1)(1 + n_2) \dots (1 + n_k). \end{aligned}$$

Hence, we get

$$|a - x| > \frac{|a_k - x_k|}{4(1 + n_1)^2(1 + n_2)^2 \dots (1 + n_k)^2}$$

To estimate $|a_k - x_k|$, consider

$$\begin{aligned} a_k - x_k &= \frac{1}{n_{k+1} + a_{k+1}} - \frac{1}{m_{k+1} + x_{k+1}} = \frac{m_{k+1} - n_{k+1} + x_{k+1} - a_{k+1}}{(n_{k+1} + a_{k+1})(m_{k+1} + x_{k+1})} \\ &> \frac{m_{k+1} - n_{k+1} + x_{k+1} - a_{k+1}}{(1 + n_{k+1})(1 + m_{k+1})}. \end{aligned}$$

Now, if $m_{k+1} < n_{k+1}$ then set $m_{k+1} = n_{k+1} - t$ with $t \geq 1$. Then one has

$$|a_k - x_k| > \frac{|-t + x_{k+1} - a_{k+1}|}{(1 + n_{k+1})(1 + n_{k+1} - t)} > \frac{a_{k+1}}{(1 + n_{k+1})^2}$$

On the other hand, if $3n_{k+1} \geq m_{k+1} > n_{k+1}$ then

$$|a_k - x_k| > \frac{|1 + x_{k+1} - a_{k+1}|}{(1 + n_{k+1})(1 + 3n_{k+1})} > \frac{1 - a_{k+1}}{3(1 + n_{k+1})^2},$$

and if $m_{k+1} > 3n_{k+1}$ then

$$|a_k - x_k| = \frac{1 - \frac{n_{k+1}}{m_{k+1}} + \frac{x_{k+1}}{m_{k+1}} - \frac{a_{k+1}}{m_{k+1}}}{(1 + n_{k+1})(1 + \frac{1}{m_{k+1}})} > \frac{1}{6(1 + n_{k+1})}$$

So one has

$$|a_k - x_k| > \frac{a_{k+1}(1 - a_{k+1})}{6(1 + n_{k+1})^2},$$

which gives the estimation from below

$$|a - x| > \frac{a_{k+1}(1 - a_{k+1})}{24(1 + n_1)^2(1 + n_2)^2 \dots (1 + n_k)^2(1 + n_{k+1})^2},$$

estimation obtained under the assumption that the continued fraction expansions of x and a coincide up until the k th term and differ for the $k + 1$ th term.

Now we have the crude estimate

$$\frac{1}{n_{k+2} + \frac{1}{n_{k+3} + 1}} > a_{k+1} > \frac{1}{1 + n_{k+2}} \implies a_{k+1}(1 - a_{k+1}) > \frac{1}{(1 + n_{k+2})^2} \frac{1}{(1 + n_{k+3})^2}.$$

which gives

$$|a - x| > \frac{1}{24(1 + n_1)^2(1 + n_2)^2 \dots (1 + n_{k+2})^2(1 + n_{k+3})^2},$$

Now put $N_k := \sum_{i=1}^k n_i$, and $\mu_k := N/k$. Then

$$(1 + n_1)^2(1 + n_2)^2 \dots (1 + n_k)^2 \leq (1 + \mu_k)^{2k} \leq (2\mu_k)^{2k}$$

The last inequality follows from the fact that $\mu_k \geq 1$ for all k , since $n_i \geq 1$ for all i . We finally obtain the estimate

$$|a - x| > \frac{1}{24}(2\mu_{k+3})^{-2(k+3)} = \frac{1}{24} \exp\{-2(k+3) \log 2\mu_{k+3}\}. \quad \square$$

On the other hand, if the c.f. expansions of a and x coincide up to the $k = k(x)$ th place, then the c.f. expansions of $\mathbf{J}(a)$ and $\mathbf{J}(x_i)$ coincide up to the place N_k , and by Binet's formula we have

$$|\mathbf{J}(a) - \mathbf{J}(x)| < F_{N_k}^{-2} < \sqrt{5}\phi^{-2N_k} = \sqrt{5} \exp\{-2k\mu_k \log \phi\}$$

(this estimate should be close to optimal (a.e.), since the density of 1's in the c.f. expansion of $\mathbf{J}(a)$ equals one a.e.) This gives

$$\left| \frac{\mathbf{J}(a) - \mathbf{J}(x)}{a - x} \right| < 24\sqrt{5} \exp k\{2(1 + 3/k) \log 2\mu_{k+3} - 2\mu_k \log \phi\} \implies$$

$$\left| \frac{\mathbf{J}(a) - \mathbf{J}(x)}{a - x} \right| < A \exp \left\{ 2k \log \phi (B \log 2\mu_{k+3} - \mu_k) \right\}$$

where A is some absolute constant and $B = (1+3/k)/\log \phi$ can be taken arbitrarily close to $1/\log \phi < 2.08$ by assuming k is big enough.

We see immediately that, if $a = [0, n, n, n, n, \dots]$ then μ_k is constant $= n$, and if n is taken big enough so that $2.08 \log 2n - n < 0$, then the derivative exists and is zero. This is true for $n > 4$. We don't claim that our estimations are optimal in this respect, however.

On the other hand, since $\mu_k \rightarrow \infty$ almost surely, we see that $B \log 2\mu_{k+3} - \mu_k < 0$ for k sufficiently big and the derivative exists and vanishes. This is because by choosing a sufficiently small neighborhood $\{|x - a| < \delta\}$, we can guarantee that $k = k(x)$ is always greater than a given number for any x in this neighborhood. This concludes the proof of the theorem.

Note that, if $\mu_k \rightarrow \infty$ then the average partial quotient of $\mathbf{J}(a)$ tends to 1, and \mathbf{J} is not differentiable at $\mathbf{J}(a)$. In other words, \mathbf{J} is almost surely not differentiable at $\mathbf{J}(a)$. In the same vein, the derivative of \mathbf{J} at $a = [0, n, n, n, n, \dots]$ vanish for $n > 4$, and we see that \mathbf{J} is not differentiable at $\mathbf{J}(a) = [0, 1_{n-1}, \overline{2, n-2}]$ or at best it will be of infinite slope at this point.
